Cryptographic Message Syntax (CMS) Symmetric Key Package Content Type

Abstract

This document defines the symmetric key format content type. It is transport independent. The Cryptographic Message Syntax (CMS) can be used to digitally sign, digest, authenticate, or encrypt this content type.

Status of This Memo

This is an Internet Standards Track document.

This document is a product of the Internet Engineering Task Force (IETF). It represents the consensus of the IETF community. It has received public review and has been approved for publication by the Internet Engineering Steering Group (IESG). Further information on Internet Standards is available in Section 2 of RFC 5741.

Information about the current status of this document, any errata, and how to provide feedback on it may be obtained at http://www.rfc-editor.org/info/rfc6031.

1. Introduction

This document defines the symmetric key format content type. It is transport independent. The Cryptographic Message Syntax (CMS) [RFC5652] can be used to digitally sign, digest, authenticate, or encrypt this content type.

The use cases that motivated the attributes in this work are elaborated in [RFC6030]. They are omitted to avoid duplication.

This document also includes ASN.1 definitions of the Extensible Markup Language (XML) element and attributes defined in [RFC6030].

1.1. Requirements Terminology

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in [RFC2119].

1.2. ASN.1 Syntax Notation

The key package is defined using the ASN.1 in [X.680], [X.681], [X.682], and [X.683].

2. Symmetric Key Package Content Type

The symmetric key package content type is used to transfer one or more plaintext symmetric keys from one party to another. A symmetric key package MAY be encapsulated in one or more CMS protecting content types. This content type MUST be Distinguished Encoding Rules (DER) encoded [X.690].

The symmetric key package content type has the following syntax:

```plaintext
cryptographic-message CONTENT-TYPE ::= { TYPE SymmetricKeyPackage IDENTIFIED BY id-ct-KP-sKeyPackage }

id-ct-KP-sKeyPackage OBJECT IDENTIFIER ::= 
{ iso(1) member-body(2) us(840) rsadsi(113549) pkcs(1) pkcs9(9) smime(16) ct(1) 25 }

SymmetricKeyPackage ::= SEQUENCE {
  version           KeyPkgVersion DEFAULT v1,
  sKeyPkgAttrs  [0] SEQUENCE SIZE (1..MAX) OF Attribute
  {{ SKeyPkgAttributes }} OPTIONAL,
  sKeys             SymmetricKeys,
  ...
}
```
SymmetricKeys ::= SEQUENCE SIZE (1..MAX) OF OneSymmetricKey

OneSymmetricKey ::= SEQUENCE {
    sKeyAttrs  SEQUENCE SIZE (1..MAX) OF Attribute
        {{ SKeyAttributes }}  OPTIONAL,
    sKey       OCTET STRING OPTIONAL
    ( WITH COMPONENTS { ..., sKeyAttrs PRESENT } |
      WITH COMPONENTS { ..., sKey PRESENT } )
}

KeyPkgVersion ::= INTEGER  { v1(1) } ( v1, ... )

The SymmetricKeyPackage fields are used as follows:

- version identifies the version of the symmetric key package content
  structure. For this version of the specification, the default
  value, v1, MUST be used.

- sKeyPkgAttrs optionally provides attributes that apply to all of
  the symmetric keys in the package. The SKeyPkgAttributes
  information object set restricts the attributes allowed in
  sKeyPkgAttrs. If an attribute appears here, then it MUST NOT also
  be included in sKeyAttrs.

- sKeys contains a sequence of OneSymmetricKey values. This
  structure is discussed below.

The OneSymmetricKey fields are used as follows:

- sKeyAttrs optionally provides attributes that apply to one
  symmetric key. The SKeyAttributes information object set restricts
  the attributes permitted in sKeyAttrs. If an attribute appears
  here, then it MUST NOT also be included in sKeyAttrs.

- sKey optionally contains the key value encoded as an OCTET STRING.

The OneSymmetricKey field MUST include sKeyAttrs, sKey, or sKeyAttrs
and sKey.

3. PSKC Attributes

The following attributes are defined to assist those using the
symmetric key package defined in this document as part of a Dynamic
Symmetric Key Provision Protocol (DSKPP) [RFC6063] with Portable
Symmetric Key Container (PSKC) attributes. [RFC6030] should be
consulted for the definitive attribute descriptions. The attributes
fall into three categories. The first category includes attributes
that apply to a key package, and these attributes will generally
appear in sKeyPkgAttrs. The second category includes attributes that
apply to a particular key, and these attributes will generally appear in sKeyAttrs. The third category includes attributes that apply to a key policy. Of the attributes defined, only the Key Identifier (Section 3.2.1) and Algorithm (Section 3.2.2) key attributes MUST be included. All other attributes are OPTIONAL.

Like PSKC, the Symmetric Key Content Type supports extensibility. Primarily, this is accomplished through the definition and inclusion of new attributes, but in some instances in which the attribute contains more than one type, the ASN.1 "..." extensibility mechanism is employed.

A straightforward approach to conversion from XML types to ASN.1 is employed. The <xs:string> type converts to UTF8String; the XML <xs:dateTime> type converts to GeneralizedTime; and the XML integer types convert to INTEGER or BinaryTime [RFC6019].

3.1. PSKC Key Package Attributes

PSKC key package attributes apply to an entire key package. These attributes can be categorized by two different attribute collections: device information and cryptographic module attributes. All of these key package attributes are OPTIONAL.

3.1.1. Device Information Attributes

Device Information attributes, when taken together, MUST uniquely identify a device to which the Symmetric Key Package is provisioned.

3.1.1.1. Manufacturer

The Manufacturer attribute indicates the manufacturer of the device. Values for Manufacturer MUST be taken from either [OATHMAN] prefixes (i.e., the left column) or from the IANA Private Enterprise Number Registry [IANAPENREG], using the Organization value. When the value is taken from [OATHMAN] "oath." MUST be prepended to the value (e.g., "oath.<values from [OATHMAN]>"). When the value is taken from [IANAPENREG], "iana." MUST be prepended to the value (e.g., "iana.<Organization value from [IANAPENREG]>"). The attribute definition is as follows:

```
at-pskc-manufacturer ATTRIBUTE ::= {
    TYPE UTF8String IDENTIFIED BY id-pskc-manufacturer 
}

id-pskc-manufacturer OBJECT IDENTIFIER ::= { id-pskc 1 }
```
3.1.1.2. Serial Number

The Serial Number attribute indicates the serial number of the device. The attribute definition is as follows:

\[ \text{at-pskc-serialNo ATTRIBUTE ::= { } } \]
\[ \text{TYPE UTF8String IDENTIFIED BY id-pskc-serialNo } \]
\[ \text{id-pskc-serialNo OBJECT IDENTIFIER ::= { id-pskc 2 } } \]

3.1.1.3. Model

The Model attribute indicates the model of the device. The attribute definition is as follows:

\[ \text{at-pskc-model ATTRIBUTE ::= { } } \]
\[ \text{TYPE UTF8String IDENTIFIED BY id-pskc-model } \]
\[ \text{id-pskc-model OBJECT IDENTIFIER ::= { id-pskc 3 } } \]

3.1.1.4. Issue Number

The Issue Number attribute contains an issue number to distinguish between two devices with the same serial number. The attribute definition is as follows:

\[ \text{at-pskc-issueNo ATTRIBUTE ::= { } } \]
\[ \text{TYPE UTF8String IDENTIFIED BY id-pskc-issueNo } \]
\[ \text{id-pskc-issueNo OBJECT IDENTIFIER ::= { id-pskc 4 } } \]

3.1.1.5. Device Binding

The Device Binding attribute provides an opaque identifier that allows keys to be bound to the device or to a class of devices.

When loading keys into a device, the attribute’s value MUST be checked against information provided to the user via out-of-band mechanisms. The implementation then ensures that the correct device or class of device is being used with respect to the provisioned key.

\[ \text{at-pskc-deviceBinding ATTRIBUTE ::= { } } \]
\[ \text{TYPE UTF8String IDENTIFIED BY id-pskc-deviceBinding } \]
\[ \text{id-pskc-deviceBinding OBJECT IDENTIFIER ::= { id-pskc 5 } } \]
3.1.1.6. Device Start Date

When included in sKeyPkgAttrs, the Device Start Date attribute indicates the start date for a device. The date MUST be represented in a form that matches the dateTime production in "canonical representation" [XMLSCHEMA]. Implementations SHOULD NOT rely on time resolution finer than milliseconds and MUST NOT generate time instants that specify leap seconds. Keys that are on the device SHOULD only be used when the current date is on or after the device start date. The attribute definition is as follows:

```
 at-pskc-deviceStartDate ATTRIBUTE ::= {
   TYPE GeneralizedTime IDENTIFIED BY id-pskc-deviceStartDate }
 id-pskc-deviceStartDate OBJECT IDENTIFIER ::= { id-pskc 6 }
```

Note that usage enforcement of the keys with respect to the dates MAY only happen on the validation server as some devices, such as smart cards, do not have an internal clock. Systems thus SHOULD NOT rely upon the device to enforce key usage date restrictions.

3.1.1.7. Device Expiry Date

When included in sKeyPkgAttrs, the Device Expiry Date attribute indicates the expiry date for a device. The date MUST be represented in a form that matches the dateTime production in "canonical representation" [XMLSCHEMA]. Implementations SHOULD NOT rely on time resolution finer than milliseconds and MUST NOT generate time instants that specify leap seconds. Keys that are on the device SHOULD only be used when the current date is before the device expiry date. The attribute definition is as follows:

```
 at-pskc-deviceExpiryDate ATTRIBUTE ::= {
   TYPE GeneralizedTime IDENTIFIED BY id-pskc-deviceExpiryDate }
 id-pskc-deviceExpiryDate OBJECT IDENTIFIER ::= { id-pskc 7 }
```

Note that usage enforcement of the keys with respect to the dates MAY only happen on the validation server as some devices, such as smart cards, do not have an internal clock. Systems thus SHOULD NOT rely upon the device to enforce key usage date restrictions.

3.1.1.8. Device User Id

The Device User Id attribute indicates the user with whom the device is associated using a distinguished name, as defined in [RFC4514]. For example: UID=jsmith,DC=example,DC=net. The attribute definition is as follows:
3.1.2. Cryptographic Module Information Attributes

Cryptographic Module attributes uniquely identify a cryptographic module. This is useful when the device contains more than one cryptographic module. At this time, only one attribute is defined.

3.1.2.1. Cryptographic Module Identifier

When included in sKeyPkgAttrs, the Cryptographic Module Identifier attribute uniquely identifies the cryptographic module to which the key is being or was provisioned. The attribute definition is as follows:

\[
\text{at-pskc-moduleId ATTRIBUTE ::= \{ \\
\quad \text{TYPE UTF8String IDENTIFIED BY id-pskc-moduleId} \}}
\]

\[
\text{id-pskc-moduleId OBJECT IDENTIFIER ::= \{ id-pskc 8 \}}
\]

3.2. PSKC Key Attributes

PSKC key attributes apply to a specific key. As noted earlier, the Key Identifier (Section 3.2.1) and Algorithm (Section 3.2.2) key attributes are REQUIRED. All other attributes are OPTIONAL.

3.2.1. Key Identifier

When included in sKeyAttrs, the Key Identifier attribute identifies the key in the context of key provisioning exchanges between two parties. This means that if PSKC is used in multiple interactions between a sending and receiving party, using different containers referencing the same keys, the KeyId MUST use the same KeyId values (e.g., after initial provisioning, if a system wants to update key metadata values in the other system, the KeyId value of the key where the metadata is to be updates MUST be the same as the original KeyId value provisioned). The attribute definition is as follows:
3.2.2. Algorithm

The Algorithm attribute uniquely identifies the PSKC algorithm profile. [RFC6030] defines two algorithm profiles "HOTP" and "PIN". The attribute definition is as follows:

at-pskc-algorithm ATTRIBUTE ::= {
  TYPE UTF8String IDENTIFIED BY id-pskc-algorithm }

id-pskc-algorithm OBJECT IDENTIFIER ::= { id-pskc 10 }

3.2.3. Issuer

The Issuer attribute names the entity that issued the key. The attribute definition is as follows:

at-pskc-issuer ATTRIBUTE ::= {
  TYPE UTF8String IDENTIFIED BY id-pskc-issuer }

id-pskc-issuer OBJECT IDENTIFIER ::= { id-pskc 11 }

3.2.4. Key Profile Identifier

The Key Profile Identifier attribute carries a unique identifier used between the sending and receiving parties to establish a set of key attribute values that are not transmitted within the container but are agreed upon between the two parties out of band. This attribute will then represent the unique reference to a set of key attribute values.

at-pskc-keyProfileId ATTRIBUTE ::= {
  TYPE UTF8String IDENTIFIED BY id-pskc-keyProfileId }

id-pskc-keyProfileId OBJECT IDENTIFIER ::= { id-pskc 12 }

3.2.5. Key Reference Identifier

The Key Reference attribute refers to an external key to be used with a key derivation scheme and no specific key value (secret) is transported; only the reference to the external master key is used (e.g., the PKCS #11 key label).
RFC 6031         CMS Symmetric Key Package Content Type    December 2010

at-pskc-keyReference ATTRIBUTE ::= {
    TYPE UTF8String IDENTIFIED BY id-pskc-keyReference }

id-pskc-keyReference OBJECT IDENTIFIER ::= { id-pskc 13 }

3.2.6.   Friendly Name

The Friendly Name attribute contains a human-readable name for the
secret key. The attribute definition is as follows:

at-pskc-friendlyName ATTRIBUTE ::= {
    TYPE FriendlyName IDENTIFIED BY id-pskc-friendlyName }

id-pskc-friendlyName OBJECT IDENTIFIER ::= { id-pskc 14 }

The Friendly Name attribute has the following syntax:

FriendlyName ::= SEQUENCE {
    friendlyName        UTF8String,
    friendlyNameLangTag UTF8String OPTIONAL }

The text is encoded in UTF-8 [RFC3629], which accommodates most of
the world’s writing systems. The friendlyNameLangTag field
identifies the language used to express the friendlyName. When the
friendlyNameLangTag field is absent, English, whose associated
language tag is "en", is used. The value of the friendlyNameLangTag
field MUST be a language tag, as described in [RFC5646].

3.2.7.   Algorithm Parameters

The Algorithm Parameters attribute contains parameters that influence
the result of the algorithmic computation, for example, response
truncation and format in One-Time Password (OTP) and
Challenge/Response (CR) algorithms.

at-pskc-algorithmParameters ATTRIBUTE ::= {
    TYPE PSKCAlgorithmParameters
    IDENTIFIED BY id-pskc-algorithmParams }

id-pskc-algorithmParams OBJECT IDENTIFIER ::= { id-pskc 15 }

The Algorithm Parameters attribute has the following syntax:

PSKCAlgorithmParameters ::= CHOICE {
    suite                UTF8String,
    challengeFormat  [0] ChallengeFormat,
    responseFormat   [1] ResponseFormat,
    ... }

Turner & Housley             Standards Track                   [Page 10]
ChallengeFormat ::= SEQUENCE {
  encoding     Encoding,
  checkDigit   BOOLEAN DEFAULT FALSE,
  min          INTEGER (0..MAX),
  max          INTEGER (0..MAX),
  ... } 

Encoding ::= UTF8STRING ("DECIMAL" | "HEXADECIMAL" |
"ALPHANUMERIC" | "BASE64" | "BINARY")

ResponseFormat ::= SEQUENCE {
  encoding     Encoding,
  length       INTEGER (0..MAX),
  checkDigit   BOOLEAN DEFAULT FALSE,
  ... }

The fields in PSKCAIAlgorithmParameters have the following meanings:

- Suite defines additional characteristics of the algorithm used, which are algorithm specific. For example, in an HMAC-based (Hashed Message Authentication Code) OTP algorithm it could designate the strength of the hash algorithm used (SHA1, SHA256, etc.). Please refer to the algorithm profile specification [RFC6030] for the exact semantics of the value for each algorithm profile.

- ChallengeFormat defines the characteristics of the challenge in a CR usage scenario, whereby the following fields are defined:
  - encoding specifies the encoding of the challenge accepted by the device and MUST be one of the following values: DECIMAL, HEXADECIMAL, ALPHANUMERIC, BASE64, or BINARY. The BASE64 encoding is done as in Section 4 of [RFC4648].
  - checkDigit indicates whether a device needs to check the appended Luhn check digit, as defined in [ISOIEC7812], contained in a challenge. The checkDigit MUST NOT be present if the encoding value is anything other than ‘DECIMAL’. A value of TRUE indicates that the device will check the appended Luhn check digit in a provided challenge. A value of FALSE indicates that the device will not check the appended Luhn check digit in the challenge.
o min defines the minimum size of the challenge accepted by the
device for CR mode. If encoding is ‘DECIMAL’, ‘HEXADECIMAL’, or
‘ALPHANUMERIC’, this value indicates the minimum number of
digits/characters. If encoding is ‘BASE64’ or ‘BINARY’, this
value indicates the minimum number of bytes of the unencoded
value.

o max defines the maximum size of the challenge accepted by the
device for CR mode. If encoding is ‘DECIMAL’, ‘HEXADECIMAL’, or
‘ALPHANUMERIC’, this value indicates the maximum number of
digits/characters. If the encoding is ‘BASE64’ or ‘BINARY’,
this value indicates the maximum number of bytes of the unencoded
value.

o ResponseFormat defines the characteristics of the result of a
computation and defines the format of the OTP or the response to a
challenge. For cases where the key is a personal identification
number (PIN) value, this element contains the format of the PIN
itself (e.g., DECIMAL, length 4 for a 4 digit PIN). The following
fields are defined:

o encoding specifies the encoding of the response generated by the
device and MUST be one of the following values: DECIMAL,
HEXADECIMAL, ALPHANUMERIC, BASE64, or BINARY. BASE64 is defined
as in Section 4 of [RFC4648].

o length defines the length of the response generated by the
device. If encoding is ‘DECIMAL’, ‘HEXADECIMAL’, or
‘ALPHANUMERIC’, this value indicates the number of
digits/characters. If encoding is ‘BASE64’ or ‘BINARY’, this
value indicates the number of bytes of the unencoded value.

o checkDigit indicates whether the device needs to append a Luhn
check digit, as defined in [ISOIEC7812], to the response. This
is only valid if the encoding attribute is ‘DECIMAL’. If the
value is TRUE, then the device will append a Luhn check digit to
the response. If the value is FALSE, then the device will not
append a Luhn check digit to the response.

3.2.8. Counter

The Counter attribute contains the event counter for event-based OTP
algorithms. The attribute definition is as follows:

at-pskc-counter ATTRIBUTE ::= {
  TYPE INTEGER(0..MAX) IDENTIFIED BY id-pskc-counter }

id-pskc-counter OBJECT IDENTIFIER ::= { id-pskc 16 }

Turner & Housley Standards Track [Page 12]
3.2.9. Time

The Time attribute conveys the time for time-based OTP algorithms. If the Time Interval attribute is included, then this element carries the number of time intervals passed for a specific start point. If the time interval is used, then this element carries the number of time intervals passed from a specific start point, normally it is algorithm dependent. It uses the BinaryTime syntax from [RFC6019]. The attribute definition is as follows:

```
 at-pskc-time ATTRIBUTE ::= {
   TYPE BinaryTime IDENTIFIED BY id-pskc-time }
 id-pskc-time OBJECT IDENTIFIER ::= { id-pskc 17 }
```

3.2.10. Time Interval

The Time Interval attribute conveys the time interval value for time-based OTP algorithms in seconds (e.g., a value of 30 for this would indicate a time interval of 30 seconds). It is an integer. The attribute definition is as follows:

```
 at-pskc-timeInterval ATTRIBUTE ::= {
   TYPE INTEGER (0..MAX) IDENTIFIED BY id-pskc-timeInterval }
 id-pskc-timeInterval OBJECT IDENTIFIER ::= { id-pskc 18 }
```

3.2.11. Time Drift

The Time Drift attribute contains the device clock drift value for time-based OTP algorithms. It is an integer, either positive or negative, that indicates the number of time intervals that a validation server has established that the device clock drifted after the last successful authentication. The attribute definition is as follows:

```
 at-pskc-timeDrift ATTRIBUTE ::= {
   TYPE INTEGER (0..MAX) IDENTIFIED BY id-pskc-timeDrift }
 id-pskc-timeDrift OBJECT IDENTIFIER ::= { id-pskc 19 }
```

3.2.12. Value MAC

The Value MAC attribute is a Message Authentication Code (MAC) generated from the encrypted value in the case that the encryption algorithm does not support integrity checks (e.g., AES-CBC does not provide integrity while AES Key Wrap with a message length indicator (MLI) does). The attribute definition is as follows:
at-pskc-valueMAC ATTRIBUTE ::= {
    TYPE ValueMac IDENTIFIED BY id-pskc-valueMAC }

id-pskc-valueMAC OBJECT IDENTIFIER ::= { id-pskc 20 }

ValueMac ::= SEQUENCE {
    macAlgorithm UTF8String,
    mac          UTF8String }

The fields in ValueMac have the following meanings:

- macAlgorithm identifies the MAC algorithm used to generate the value placed in digest.
- mac is the base64-encoded, as specified in Section 4 of [RFC4648], mac value.

3.2.13. Key User Id

The Key User Id attribute indicates the user with whom the key is associated using a distinguished name, as defined in [RFC4514]. For example, UID=jsmith,DC=example,DC=net. The attribute definition is as follows:

at-pskc-keyUserId ATTRIBUTE ::= {
    TYPE UTF8String IDENTIFIED BY id-pskc-keyUserId }

id-pskc-keyUserId OBJECT IDENTIFIER ::= { id-pskc 27 }

As specified in [RFC6030], there are no semantics associated with this element, i.e., there are no checks enforcing that only a specific user can use this key. As such, this element is for informational purposes only.

3.3. Key Policy Attributes

Key policy attributes indicate a policy that can be attached to a key. These attributes are defined in the subsections that follow.

3.3.1. Key Start Date

When included in sKeyAttrs, the Key Start Date attribute indicates the start of the key’s validity period. The date MUST be represented in a form that matches the dateTime production in "canonical representation" [XMLSCHEMA]. Implementations SHOULD NOT rely on time resolution finer than milliseconds and MUST NOT generate time instants that specify leap seconds. The attribute definition is as follows:
3.3.2. Key Expiry Date

When included in sKeyAttrs, the Key Expiry Date attribute indicates the end of the key’s validity period. The date MUST be represented in a form that matches the dateTime production in "canonical representation" [XMLSCHEMA]. Implementations SHOULD NOT rely on time resolution finer than milliseconds and MUST NOT generate time instants that specify leap seconds. The attribute definition is as follows:

```
at-pskc-keyExpiryDate ATTRIBUTE ::= {
    TYPE GeneralizedTime IDENTIFIED BY id-pskc-keyExpiryDate }
```

```
id-pskc-keyExpiryDate OBJECT IDENTIFIER ::= { id-pskc 22 }
```

3.3.3. Number of Transactions

The Number of Transactions attribute indicates the maximum number of times a key carried within the package can be used. When this element is omitted, there is no restriction regarding the number of times a key can be used. The attribute definition is as follows:

```
at-pskc-noOfTransactions ATTRIBUTE ::= {
    TYPE INTEGER (0..MAX) IDENTIFIED BY id-pskc-noOfTransactions }
```

```
id-pskc-noOfTransactions OBJECT IDENTIFIER ::= { id-pskc 23 }
```

3.3.4. Key Usage

The Key Usage attribute constrains the intended usage of the key. The recipient MUST enforce the key usage. The attribute definition is as follows:

```
at-pskc-keyUsage ATTRIBUTE ::= {
    TYPE PSKCKeyUsages IDENTIFIED BY id-pskc-keyUsages }
```

```
id-pskc-keyUsages OBJECT IDENTIFIER ::= { id-pskc 24 }
```

```
PSKCKeyUsages ::= SEQUENCE OF PSKCKeyUsage

PSKCKeyUsage ::= UTF8String ("OTP" | "CR" | "Encrypt" |
                        "Integrity" | "Verify" | "Unlock" | "Decrypt" |
                        "KeyWrap" | "Unwrap" | "Derive" | "Generate")
```

Turner & Housley Standards Track [Page 15]
The fields in PSKCKKeyUsage have the following meanings:

- OTP: The key MUST only be used for OTP generation.
- CR: The key MUST only be used for Challenge/Response purposes.
- Encrypt: The key MUST only be used for data encryption purposes.
- Integrity: The key MUST only be used to generate a keyed message digest for data integrity or authentication purposes.
- Verify: The key MUST only be used to verify a keyed message digest for data integrity or authentication purposes (is the converse of Integrity).
- Unlock: The key MUST only be used for an inverse Challenge/Response in the case in which a user has locked the device by entering an incorrect PIN too many times (for devices with PIN-input capability).
- Decrypt: The key MUST only be used for data decryption purposes.
- KeyWrap: The key MUST only be used for key wrap purposes.
- Unwrap: The key MUST only be used for key unwrap purposes.
- Derive: The key MUST only be used with a key derivation function to derive a new key (see also Section 8.2.4 of [NIST800-57]).
- Generate: The key MUST only be used to generate a new key based on a random number and the previous value of the key (see also Section 8.1.5.2.1 of [NIST800-57]).

3.3.5. PIN Policy

The PIN Policy attribute allows policy about the PIN usage to be associated with the key. The attribute definition is as follows:

```plaintext
at-pskc-pinPolicy ATTRIBUTE ::= {
  TYPE PINPolicy IDENTIFIED BY id-pskc-pinPolicy }

id-pskc-pinPolicy OBJECT IDENTIFIER ::= { id-pskc 25 }
```
PINPolicy ::= SEQUENCE {
  pinKeyId          [0] UTF8String OPTIONAL,
  pinUsageMode      [1] PINUsageMode,
  maxFailedAttempts [2] INTEGER (0..MAX) OPTIONAL,
  minLength         [3] INTEGER (0..MAX) OPTIONAL,
  maxLength         [4] INTEGER (0..MAX) OPTIONAL,
  pinEncoding       [5] Encoding OPTIONAL }

PINUsageMode ::= UTF8String ("Local" | "Prepend" | "Append" | "Algorithmic")

The fields in PIN Policy have the following meanings:

- **pinKeyId** uniquely identifies the key held within this container that contains the value of the PIN that protects the key.
- **pinUsageMode** indicates the way the PIN is used during the usage of the key. The following values are defined in [RFC6030]: Local, Prepend, Append, and Algorithmic.
- **maxFailedAttempts** indicates the maximum number of times the PIN may be entered incorrectly before it MUST NOT be possible to use the key anymore (reasonable values are in the positive integer range of at least 2 and no more than 10).
- **minLength** indicates the minimum length of a PIN that can be set to protect the associated key. It MUST NOT be possible to set a PIN shorter than this value. If pinEncoding is ‘DECIMAL’, ‘HEXADECIMAL’, or ‘ALPHANUMERIC’, this value indicates the number of digits/characters. If pinEncoding is ‘BASE64’ or ‘BINARY’, this value indicates the number of bytes of the unencoded value.
- **maxLength** indicates the maximum length of a PIN that can be set to protect this key. It MUST NOT be possible to set a PIN longer than this value. If pinEncoding is ‘DECIMAL’, ‘HEXADECIMAL’, or ‘ALPHANUMERIC’, this value indicates the number of digits/characters. If the pinEncoding is ‘BASE64’ or ‘BINARY’, this value indicates the number of bytes of the unencoded value.
- **pinEncoding** is based on Encoding, which is defined in Section 3.2.7, and specifies encoding of the PIN and MUST be one of the following values: DECIMAL, HEXADECIMAL, ALPHANUMERIC, BASE64, or BINARY.

If pinUsageMode is set to "Local", then the device MUST enforce the restriction indicated in maxFailedAttempts, minLength, maxLength, and pinEncoding; otherwise, it MUST be enforced on the server side.
4. Key Encoding

Two parties receiving the same key as an sKey OCTET STRING must make use of the key in exactly the same way in order to interoperate. To ensure that this occurs, it is necessary to define a correspondence between the abstract syntax of sKey and the notation in the standard algorithm description that defines how the key is used. The next sections establish that correspondence for the AES algorithm [FIPS197] and the Triple Data Encryption Algorithm (TDEA or Triple DES) [SP800-67].

4.1. AES Key Encoding

[FIPS197], Section 5.2, titled "Key Expansion", uses the input key as an array of bytes indexed starting at 0. The first octet of sKey SHALL become the key byte in the AES, labeled index 0 in [FIPS197]; the succeeding octets of sKey SHALL become key bytes in AES, in increasing index order.

Proper parsing and key load of the contents of sKey for AES SHALL be determined by using the following sKey OCTET STRING to generate and match the key expansion test vectors in [FIPS197], Appendix A, for AES Cipher Key: 2b 7e 15 16 28 ae d2 a6 ab f7 15 88 09 cf 4f 3c

<table>

<tr>
<td>04 16</td>
<td>2b 7e 15 16 28 ae d2 a6 ab f7 15 88 09 cf 4f 3c</td>
</tr>
</tbody>
</table>

4.2. Triple-DES Key Encoding

A Triple-DES key consists of three keys for the cryptographic engine (Key1, Key2, and Key3) that are each 64 bits (56 key bits and 8 parity bits); the three keys are also collectively referred to as a key bundle [SP800-67]. A key bundle may employ either two or three independent keys. When only two independent keys are employed (called two-key Triple DES), the same value is used for Key1 and Key3.

Each key in a Triple-DES key bundle is expanded into a key schedule according to a procedure defined in [SP800-67], Appendix A. That procedure numbers the bits in the key from 1 to 64, with number 1 being the leftmost, or most significant bit (MSB). The first octet of sKey SHALL be bits 1 through 8 of Key1 with bit 1 being the MSB. The second octet of sKey SHALL be bits 9 through 16 of Key1, and so forth, so that the trailing octet of sKey SHALL be bits 57 through 64 of Key3 (or Key2 for two-key Triple DES).
Proper parsing and key load of the contents of sKey for Triple DES SHALL be determined by using the following sKey OCTET STRING to generate and match the key expansion test vectors in [SP800-67], Appendix B, for the key bundle:

Key1 = 0123456789ABCDEF
Key2 = 23456789ABCDEF01
Key3 = 456789ABCDEF0123

<table>
<thead>
<tr>
<th>Tag Length Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>04 24 0123456789ABCDEF 23456789ABCDEF01 456789ABCDEF0123</td>
</tr>
</tbody>
</table>

5. Security Considerations

Implementers of this protocol are strongly encouraged to consider generally accepted principles of secure key management when integrating this capability within an overall security architecture.

The symmetric key package contents are not protected. This content type can be combined with a security protocol to protect the contents of the package. One possibility is to include this content type in place of a PSKC package in [RFC6063] exchanges. In this case, the algorithm requirements are found in those documents. Another possibility is to encapsulate this content type in a CMS [RFC5652] protecting content type.

6. IANA Considerations

This document makes use of object identifiers to identify a CMS content type (Appendix A.1), the ASN.1 version of the PSKC attributes (Appendix A.2), and the ASN.1 modules found in Appendix A.1 and A.2.

All OIDs are registered in an arc delegated by RSADSI to the SMIME Working Group.

Appendix A. ASN.1 Module

This appendix provides the normative ASN.1 definitions for the structures described in this specification using ASN.1 as defined in [X.680], [X.681], [X.682], and [X.683].
