IGP Unreachable Prefix Announcement
draft-ietf-lsr-igp-ureach-prefix-announce-11

Abstract

Summarization is often used in multi-area or multi-domain networks to improve network efficiency and scalability. With summarization in place, there is a need to signal loss of reachability to an individual prefix covered by the summary. This enables fast convergence by steering traffic, when applicable, away from the node which owns the prefix and is no longer reachable.

This document specifies protocol mechanisms in IS-IS and OSPF, together with two new flags, to advertise such prefix reachability loss.

The term OSPF in this document is used to refer to both OSPFv2 and OSPFv3.

Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in BCP 14 [RFC2119][RFC8174] when, and only when, they appear in all capitals, as shown here.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <https://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on 29 March 2026.

1. Introduction

Link-state Interior Gateway Protocols (IGPs) protocols like Intermediate System to Intermediate System (IS-IS) [ISO10589], Open Shortest Path First version 2 (OSPFv2) [RFC2328], and Open Shortest Path First version 3 (OSPFv3) [RFC5340] are primarily used to distribute routing information between routers belonging to a single Autonomous System (AS) and to calculate the reachability for IPv4 or IPv6 prefixes advertised by the individual nodes inside the AS. Each node advertises the state of its local adjacencies, connected prefixes, capabilities, etc. The collection of these states from all the routers inside the area form a link-state database (LSDB) that describes the topology of the area and holds additional state information about the prefixes, router capabilities, etc.

The growth of networks running a link-state routing protocol results in the addition of more state which leads to scalability and convergence challenges. The organization of networks into levels/areas and IGP domains helps limit the scope of link-state information within certain boundaries. However, the state related to prefix reachability often requires propagation across a multi-area/level and/or multi-domain IGP network. IGP summarization is a network engineering technique for combining multiple smaller, contiguous IP networks into a single, larger summary route. Techniques such as summarization have been used traditionally to address the scale challenges associated with advertising prefix state outside of the local area/domain. However, this results in suppression of the individual prefix state that is useful for triggering fast-convergence mechanisms outside of the IGPs - e.g., Border Gateway Protocol (BGP) Prefix Independent Convergence (PIC) [I-D.ietf-rtgwg-bgp-pic].

Similarly, when a router needs to be taken out of service for maintenance, the traffic is drained from the node before taking it down. This is typically achieved by setting the OVERLOAD bit together with using a high metric for all prefixes advertised by the node in IS-IS. In OSPFv2 using the cost of MaxLinkMetric for all non-stub links in the router-LSA [RFC6987], or H-bit [RFC8770], and R-bit for OSPFv3 [RFC5340] are mechanisms available for that purpose.

When prefixes from such node are summarized by an Area Border Router (ABR) or Autonomous System Boundary Router (ASBR), nodes outside of the area or domain are unaware of these summarized prefixes becoming unreachable. This document proposes protocol extensions to carry information about such prefixes in a backward compatible manner.

This document does not define how to advertise a prefix that is not reachable for routing. That has been defined for IS-IS in [RFC5305] and [RFC5308], for OSPFv2 in [RFC2328], and for OSPFv3 in [RFC5340].

This document defines a method to signal a specific reason for which the prefix was advertised with the metric that excludes it from the route calculation. This is done to distinguish it from any other possible cases, where such metric advertisement may be used.

IGP protocols typically only advertise the reachability of the prefix. Prefix that was previously advertised as reachable is made unreachable just by withdrawing the previous advertisement of the prefix. Some of the use cases mentioned earlier in this section require to signal unreachability for a prefix for which the reachability was not explicitly signaled previously, because it was covered by the reachability of the summary prefix.

This document defines two new flags in IS-IS, OSPFv2, and OSPFv3. These flags provide the support for advertising prefix unreachability, together with the reason for which the unreachability is advertised. The functionality being described is called Unreachable Prefix Announcement (UPA).

This document also defines how the UPA is propagated across IS-IS levels and OSPF areas.

The term OSPF in this document is used to cover both OSPFv2 and OSPFv3 protocols.

2. Generation of the UPA

UPA MAY be generated by an ABR or ASBR for a prefix that is summarized by the summary prefix originated by an ABR or ASBR in the following cases:

1. Reachability of a prefix that was reachable earlier was lost.
2. For any of the planned maintenance cases:
 - if the node originating the prefix is signalling the overload state in IS-IS, or or H-bit in OSPFv2 [RFC8770], or R-bit in OSPFv3 [RFC5340] .
 - the metric to reach the prefix from an ABR or ASBR crosses the configured threshold.

Generation as well as propagation of the UPA at an ABR or ASBR is optional and SHOULD be controlled by a configuration knob. It SHOULD be disabled by default.

Implementations MAY limit the UPA generation as well as propagation to specific prefixes, e.g. host prefixes, SRv6 locators, or similar. Such filtering is optional and SHOULD be controlled via configuration.

The intent of UPA is to provide an event driven signal of the transition of a destination from reachable to unreachable. It is not intended to advertise a persistent state.

ABR or ASBR MUST withdraw the previously advertised UPA when the reason for which the UPA was generated ceases - e.g. prefix reachability was restored or its metric has changed such that it is below a configured threshold value.

Even if the reasons persist, UPA advertisements SHOULD be withdrawn after some amount of time, that would provide sufficient time for UPA to be flooded network-wide and acted upon by receiving nodes, but limits the presence of UPA in the network. The time the UPA is kept in the network SHOULD also reflect the intended use-case for which the UPA was advertised. Not withdrawing the UPA would result in stale information being kept in the link state database of all routers in the area.

Implementations SHOULD provide a configuration option to specify the UPA lifetime at the originating ABR or ASBR.

As UPA advertisements in IS-IS are advertised in existing Link State PDUs (LSPs) and the unit of flooding in IS-IS is an LSP, it is RECOMMENDED that, when possible, UPAs are advertised in LSPs dedicated to this type of advertisement. This will minimize the number of LSPs which need to be updated when UPAs are advertised and withdrawn.

In OSPFv2 and OSPFv3, each inter-area and external prefix is advertised in its own LSA, so the above consideration does not apply to OSPFv2 and OSPFv3.

It is also RECOMMENDED that implementations limit the number of UPA advertisements which can be originated at a given time to limit the number of UPAs present in the network at any given point of time. UPA implementations SHOULD provide a configuration option to limit the number of such UPAs.

3. Supporting UPA in IS-IS

[RFC5305] defines the encoding for advertising IPv4 prefixes using 4 octets of metric information and its section 4 specifies:

"If a prefix is advertised with a metric larger than MAX_PATH_METRIC (0xFE000000, see paragraph 3.0), this prefix MUST NOT be considered during the normal SPF computation. This allows advertisement of a prefix for purposes other than building the normal IP routing table."

Similarly, [RFC5308] defines the encoding for advertising IPv6 prefixes using 4 octets of metric information and its section 2 states:

"...if a prefix is advertised with a metric larger than MAX_V6_PATH_METRIC (0xFE000000), this prefix MUST NOT be considered during the normal Shortest Path First (SPF) computation. This will allow advertisement of a prefix for purposes other than building the normal IPv6 routing table."

This functionality can be used to advertise a prefix (IPv4 or IPv6) in a manner which indicates that reachability has been lost - and to do so without requiring all nodes in the network to be upgraded to support the functionality.

3.1. Advertisement of UPA in IS-IS

Existing nodes in a network that do not support UPA will not use UPAs during the route calculation, but will continue to flood them within the area. This allows flooding of such advertisements to occur without the need to upgrade all nodes in a network to support this specification.

Those ABRs or ASBRs which are responsible for propagating UPA advertisements into other areas or domains, are also expected to recognise UPA advertisements.

As per the definitions referenced in the preceding section, any prefix advertisement with a metric value greater than 0xFE000000 can be used for purposes other than normal routing calculations. Such metric MUST be used when advertising UPA in IS-IS.

[RFC7370] introduced the IS-IS Sub-TLVs for TLVs Advertising Prefix Reachability registry which lists TLVs for advertising different types of prefix reachability (that list at the time of publication of this document is below). UPA in IS-IS is supported for prefixes advertised in all such TLVs identified by that registry, e.g.:

- SRv6 Locator [RFC9352]
- Extended IP reachability [RFC5305]
- MT IP Reach [RFC5120]
- IPv6 IP Reach [RFC5308]
- MT IPv6 IP Reach [RFC5120]
- IPv4 Algorithm Prefix Reachability TLV [RFC9502]
- IPv6 Algorithm Prefix Reachability TLV [RFC9502]

3.2. Signaling UPA in IS-IS

In IS-IS a prefix can be advertised with metric higher than 0xFE000000, for various reasons. Even though in all cases the treatment of such metric is specified for IS-IS, having an explicit way to signal that the prefix was advertised in order to signal UPA is required to distinguish it from other cases where the prefix with such metric is advertised.

Two new bits in the IPv4/IPv6 Extended Reachability Attribute Flags [RFC7794] are defined:

U-Flag: - Unreachable Prefix Flag (Bit 5). When set, it indicates that the prefix is unreachable.

UP-Flag: - Unreachable Planned Prefix Flag (Bit 6). When set, this flag indicates that the prefix is unreachable due to a planned event (e.g., planned maintenance).

Originating node MUST NOT set the UP-flag without setting the U-flag.

Receiving node MUST ignore the UP-flag in the advertisement if the U-flag is not set.

The prefix that is advertised with U-Flag MUST have the metric set to a value larger than 0xFE000000. If the prefix metric is less than or equal 0xFE000000, both of these flags MUST be ignored.

3.3. Propagation of UPA in IS-IS

IS-IS L1/L2 routers, which would be responsible for propagating UPA advertisements between levels need to recognize such advertisements. Failure to do so would prevent UPA to reach the routers in the remote areas.

IS-IS allows propagation of IP prefixes in both directions between level 1 and level 2. Propagation is only done if the prefix is reachable in the source level, i.e., prefix is only propagated from a level in which the prefix is reachable. Such requirement of reachability MUST NOT be applied for UPAs, as they are propagating unreachability.

IS-IS L1/L2 routers may wish to advertise received UPAs into other areas (upwards and/or downwards). When propagating UPAs the original metric value MUST be preserved. The cost to reach the originator of the received UPA MUST NOT be considered when readvertising the UPA.

4. Supporting UPA in OSPF

[RFC2328] Appendix B defines the following architectural constant for OSPFv2:

"LSInfinity The metric value indicating that the destination described by an LSA is unreachable. Used in summary-LSAs and AS-external-LSAs as an alternative to premature aging (see Section 14.1). It is defined to be the 24-bit binary value of all ones: 0xffffffff."

[RFC5340] Appendix B states:

"Architectural constants for the OSPF protocol are defined in Appendix B of [OSPFV2]."

indicating that these same constants are applicable to OSPFv3.

[RFC2328] section 14.1. also describes the usage of LSInfinity as a way to indicate loss of prefix reachability:

"Premature aging can also be used when, for example, one of the router's previously advertised external routes is no longer reachable. In this circumstance, the router can flush its AS-external-LSA from the routing domain via premature aging. This procedure is preferable to the alternative, which is to originate a new LSA for the destination specifying a metric of LSInfinity."

In addition, NU-bit is defined for OSPFv3 [RFC5340]. Prefixes having the NU-bit set in their PrefixOptions field are not included in the routing calculation.

UPA in OSPFv2 is supported for prefix reachability advertised via OSPFv2 Summary-LSA [RFC2328], AS-external-LSAs [RFC2328], NSSA AS-external LSA [RFC3101], and OSPFv2 IP Algorithm Prefix Reachability Sub-TLV [RFC9502].

UPA in OSPFv3 is supported for prefix reachability advertised via OSPFv3 E-Inter-Area-Prefix-LSA [RFC8362], E-AS-External-LSA [RFC8362], E-Type-7-LSA [RFC8362], and SRv6 Locator LSA [RFC9513].

For prefix reachability advertised via Inter-Area-Prefix-LSA [RFC5340], AS-External-LSA [RFC5340], NSSA-LSA [RFC5340], UPA is signaled using their corresponding extended LSAs. This requires support of the OSPFv3 Extended LSAs in a sparse mode as specified in section 6.2 of [RFC8362].

4.1. Advertisement of UPA in OSPF

If an ABR or ASBR advertises UPA in an advertisement of an inter-area or external prefix inside OSPFv2 or OSPFv3 then it MUST set the age to a value lower than MaxAge and set the metric to LSInfinity.

UPA flooding inside the area follows the existing standard procedures defined by OSPFv2 [RFC2328] and OSPFv3 [RFC5340].

4.2. Signaling UPA in OSPF

In OSPFv2 a prefix can be advertised with metric LSInfinity, or in OSPFv3 with NU-bit set in PrefixOptions, for various reasons. Even though in all cases the treatment of such metric, or NU-bit, is specified for OSPFv2 and OSPFv3, having an explicit way to signal that the prefix was advertised in order to signal UPA is required to distinguish it from other cases where the prefix with such metric is advertised.

OSPFv2 and OSPFv3 Prefix Extended Flags Sub-TLVs been defined in [RFC9792] for advertising additional prefix attribute flags in OSPFv2 and OSPFv3.

Two new bits in Prefix Attributes Sub-TLV are defined:

U-Flag: - Unreachable Prefix Flag (Bit 0). When set, it indicates that the prefix is unreachable.

UP-Flag: - Unreachable Planned Prefix Flag (Bit 1). When set,

this flag indicates that the prefix is unreachable due to a planned event (e.g., planned maintenance).

Originating node MUST NOT set the UP-flag without setting the U-flag.

Receiving node MUST ignore the UP-flag in the advertisement if the U-flag is not set.

4.2.1. Signaling UPA in OSPFv2

OSPFv2 Prefix Extended Flags Sub-TLV [RFC9792] is a Sub-TLV of the OSPFv2 Extended Prefix TLV [RFC7684].

The prefix that is advertised with U-Flag MUST have the metric set to a value LSInfinity. If the prefix metric is not equal to LSInfinity, both of these flags MUST be ignored. For default algorithm 0 prefixes with U-Flag it is therefore REQUIRED to advertise the unreachable prefix in the base OSPFv2 LSA - e.g., OSPFv2 Summary-LSA [RFC2328], or AS-external-LSAs [RFC2328], or NSSA AS-external LSA [RFC3101].

4.2.2. Signaling UPA in OSPFv3

OSPFv3 Prefix Extended Flags Sub-TLV is defined as a Sub-TLV of the following OSPFv3 TLVs that are defined in [RFC8362]:

Intra-Area Prefix TLV

Inter-Area Prefix TLV

External Prefix TLV

The prefix that is advertised with U-Flag or UP-flag MUST have the metric set to a value LSInfinity. For default algorithm 0 prefixes, the LSInfinity MUST be set in the parent TLV. For IP Algorithm Prefixes [RFC9502], the LSInfinity MUST be set in OSPFv3 IP Algorithm Prefix Reachability sub-TLV. If the prefix metric is not equal to LSInfinity, both of these flags MUST be ignored.

The prefix that is advertised with U-Flag or UP-Flag MUST have the NU-bit set in the PrefixOptions of the parent TLV. If the NU-bit in PrefixOptions of the parent TLV is not set, both of these flags MUST be ignored.

4.3. Propagation of UPA in OSPF

OSPF ABRs, which would be responsible for propagating UPA advertisements into other areas need to recognize such advertisements. Failure to do so would prevent UPA to reach the routers in the remote areas.

Advertising prefix reachability between OSPF areas assumes prefix reachability in a source area. Such requirement of reachability MUST NOT be applied for UPAs, as they are propagating unreachability.

OSPF ABRs or ASBRs MAY advertise received UPAs between connected areas or domains. When doing so, the original LSInfinity metric value in UPA MUST be preserved. The cost to reach the originator of the received UPA MUST NOT be considered when readvertising the UPA to connected areas.

5. Processing of the UPA

Processing of the received UPAs is optional and SHOULD be controlled by the configuration at the receiver. The receiver itself, based on its configuration, decides what the UPA will be used for and what applications, if any, will be notified when UPA is received. Usage of the UPA at the receiver is outside of the scope of this document.

As an example, UPA may be used to trigger BGP PIC Edge at the receiving router [I-D.ietf-rtgwg-bgp-pic].

Applications using the UPA cannot use the absence of the UPA to infer that the reachability of the prefix is back. They must rely on their own mechanisms to verify the reachability of the remote end-points.

6. Area and Domain Partition

UPA is not meant to address an area/domain partition. When an area or domain partitions, while multiple ABRs or ASBRs advertise the same summary, each of them can only reach portion of the summarized prefix. As a result, depending on which ABR or ASBR the traffic is using to enter a partitioned area, the traffic could be either dropped or delivered to its final destination. UPA does not make the problem of an area partition any worse. In case of an area partition each of an ABRs or ASBRs will generate UPAs for the destinations for which the reachability was lost locally. As the UPA propagates to the nodes outside of a partitioned area, it may result in such nodes picking an alternative egress node for the traffic, if such alternate egress node exists. If such alternate egress node resides outside of a partitioned area, traffic will be restored. If such alternate egress node resides in a partitioned area and is covered by the

summary, the traffic will be dropped if it enters a partitioned area via an ABR or ASBR that can not reach the alternate egress node - resulting in similar behavior as without the UPA. Above is similarly applicable to a domain partition.

7. IANA Considerations

7.1. IS-IS Prefix Attribute Flags Sub-TLV

This document adds two new bits in the "IS-IS Bit Values for Prefix Attribute Flags Sub-TLV" registry:

Bit #: 5

Description: U-Flag

Reference: This document (Section 3.2).

Bit #: 6

Description: UP-Flag

Reference: This document (Section 3.2).

7.2. OSPFv2 and OSPFv3 OSPFv2 Prefix Extended Flags

This document adds two new bits in the "OSPFv2 Prefix Extended Flags" and "OSPFv3 Prefix Extended Flags" registries:

Bit #: 0

Description: U-Flag

Reference: This document (Section 4.2).

Bit #: 1

Description: UP-Flag

Reference: This document (Section 4.2).

8. Security Considerations

The use of UPAs introduces the possibility that an attacker could inject a false, but apparently valid, UPA. However, the risk of this occurring is no greater than the risk today of an attacker injecting any other type of false advertisement.

The risks can be reduced by the use of existing security extensions as described in:

- [RFC5304], [RFC5310], and [RFC7794] for IS-IS.
- [RFC2328], [RFC7474] and [RFC7684] for OSPFv2.
- [RFC5340], [RFC4552] and [RFC8362] for OSPFv3.

9. Acknowledgements

The authors would like to thank Kamran Raza, Michael MacKenzie and Luay Jalil for their contribution and support of the overall solution proposed in this document.
